

## ABSTRACT

### RNTUPLE FOR ATLAS ANALYSIS WORKFLOWS

Fatima Rodriguez, M.A.  
Department of Physics  
Northern Illinois University, 2025  
Hector de la Torre, Director

RNTuple is the new data storage format set to replace TTree at the start of the High Luminosity LHC. An investigation was conducted on how analysis workflows for ATLAS researchers will change with RNTuple. Additionally, performance studies have been conducted that demonstrate an improvement in speed and memory usage at the analysis front. Finally, different compression algorithms were tested and it was found that blah blah remains to best work with RNTuple.

## CHAPTER 1

45

### INTRODUCTION

46 Our current understanding of the building blocks of our universe is summarized with one  
47 model, called the Standard Model (SM). From the way we power our cities, to the particles  
48 that hold them together, the SM explains how the basic building blocks of matter interact,  
49 governed by the four fundamental forces. Yet, questions remain about the SM, such as  
50 why are there only three generations of fundamental particles? What is the nature of dark  
51 matter and dark energy, and how does it fit within the SM? What about the origin of the  
52 matter-antimatter asymmetry? Is there a unification theory for the fundamental forces? Is  
53 the SM complete or do other exotic particles exists? Over the years, experimental particle  
54 physicists and engineers have built technology to test the SM, either by performing precision  
55 measurements of particles and their behaviors, or by colliding particles and measuring their  
56 outputs. As a result, we have increased our confidence in the SM theory, but continue to  
57 search for answers of these remaining questions through experimental discovery.

58 A Toroidal LHC Apparatus (ATLAS) is a particle physics experiment designed to detect  
59 the high-energy particle collisions from the Large Hadron Collider (LHC). Collisions take  
60 place at a rate of more than a billion interactions per second, which is a combined data  
61 volume of about 60 million megabytes per second. However, in order to study rare processes,  
62 as shown in Figure 1.1, the LHC will have a major upgrade to increase the number of collisions  
63 by a factor of 5 to 7.5. This upgrade, called the High-Luminosity LHC, will require a new  
64 data storage format that can handle this increase in data.

65 RNTuple is the new ROOT data storage format that will be in use at the start of the  
66 HL-LHC. Due to its design, which takes advantage of modern C++ techniques, it is set to

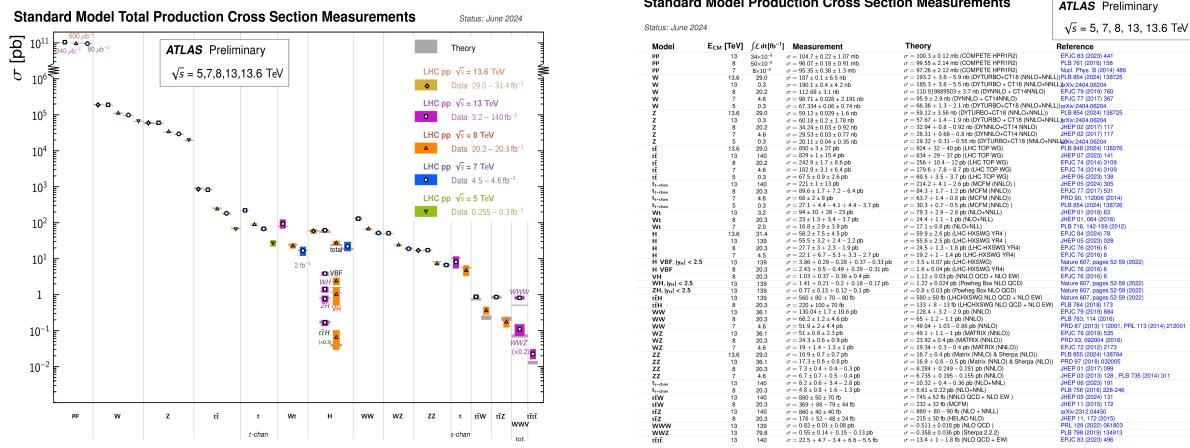

Figure 1.1: Summary of several Standard Model cross-section measurements (a) with associated references (b). The measurements are corrected for branching fractions, compared to the corresponding theoretical expectations.

improve read speedability and memory usage compared to its predecessor, TTree, and other data storage formats such as HDF5 and Parquet. At the start of this work, performance studies on RNTuple were conducted at the production level, and RNTuple was still at an experimental stage. The studies highlighted in this work investigate the performance of RNTuple on the analysis front for ATLAS workflows and serve as documentation for future RNTuple usage.

In the next chapter, I will describe the ATLAS experiment and its detector technology. In Chapter 3, I will introduce the ATLAS software and computing system, and explain our data contents. In Chapter 4, I will give an introduction to RNTuple and TTree. Examples of how RNTuple is applied in comparison to TTree will be shown. In Chapter 5, I will demonstrate the performance studies conducted for RNTuple and how they compare with TTree. In Chapter 6, I will describe the Analysis Grand Challenge (AGC) which served as a benchmark for RNTuple. Finally I will give my conclusions in Chapter 7.

80

## CHAPTER 2

81

### THE ATLAS EXPERIMENT

82        A Toroidal LHC Apparatus, mainly known as ATLAS, is a particle physics experiment  
83    located at the Large Hadron Collider near Geneva, Switzerland. ATLAS is 44 meters long  
84    and 25 meters in diameter, making it the largest detector ever constructed for a particle  
85    collider. It is designed as a general-purpose particle physics experiment, focused on precision  
86    measurements of the Standard Model. Research from ATLAS physicists has led to ground-  
87    breaking discoveries, such that of the Higgs boson.

88

### 2.1   Detector Technology

89        To do this, ATLAS has six different detecting subsystems wrapped concentrically in  
90    layers around the collision point to record the trajectory, momentum, and energy of particles.  
91    Apart, a huge magnet system bends the paths of the charged particles so that their momenta  
92    can be measured as precisely as possible. Overall, the detector tracks and identifies particles  
93    to investigate a wide range of physics.

94

#### 2.1.1   Inner Detector

95

what is its main functions
